## Acknowledgements

This project was funded by Idaho Power to address issues with Hg in the Hells Canyon Complex on the Snake River. Our project manager was Jesse Naymik. Dr. Zhong Zhang wrote the first code iteration and provided the basic background and write-up of the equations including the non-equilibrium section which is Appendix B. Dr. Reed Harris provided useful comments and feedback during the preparation of the original equations. Bernadel Garstecki worked on developing the Hg boundary conditions and implementing them in the CE-QUAL-W2 Hg model.

### Introduction

Idaho Power Company is developing strategies for improving water quality in the Hells Canyon Complex (HCC) on the Snake River (see Figure 1). The HCC includes Brownlee, Oxbow, and Hells Canyon Reservoirs. The objective of this study was to develop a computer simulation model of the HCC incorporating Hg dynamics. This modeling tool would then be used to assess strategies for water quality improvement.

FIGURE 1. THE HELLS CANYON COMPLEX ALONG THE SNAKE RIVER INCLUDING BROWNLEE RESERVOIR, OXBOW RESERVOIR, AND HELLS CANYON RESERVOIR ALONG THE IDAHO-OREGON BORDER.

This document describes the Hg model used in the water quality and hydrodynamic model developed for the HCC Snake River system. Garstecki et al. (2023) documented the eutrophication model for Brownlee, Oxbow, and Hells Canyon Reservoirs, including model setup and calibration over the period 2014-2018. This hydrodynamic and eutrophication model was a critical component of the Hg model since it relied on many internal processes, such as temperature, dissolved oxygen, organic and inorganic solids, and dissolved organic carbon.

The following topics are discussed in this report:

- The Hg module in CE-QUAL-W2
- Field data used in the HCC as Boundary Conditions to the HCC model
- Implementation of the Hg Module in CE-QUAL-W2
- Summary

### Hg Module in CE-QUAL-W2

The model domain is conceptualized as a multi-layer water column underlain by an active sediment layer (Figure 2). The active sediment layer is envisioned as a single well-mixed layer with a fixed thickness of ≈ 2-5 cm. The conceptualization is based on two important features in surface sediments. First, most methylmercury production in surface sediments typically occurs primarily within the top few cm. This is evident in vertical profiles of methylmercury concentrations in surface sediments, which typically peak near or at the surface. As sediments accumulate over time, the vertical profile continues to exhibit higher concentrations near the surface, indicating that the processes governing the location of peak concentrations (methylation and demethylation) operate on a time scale faster than the rate of sedimentation. Averaging methylmercury concentrations over deeper depths would typically underestimate the concentrations near the surface. The second reason for using a surface layer on the order of a few cm thick is that this is a typical depth for surface mixing driven by physical mixing associated with shear stress, bioturbation, and possibly gas formation and ebullition. Thus, the top few cm of the sediment bed is the primary zone interacting with overlying waters and the food web, unless strong erosion occurs. The single well-mixed layer forms the basis for the earliest toxic models like WASP (EPA, 2001). The Dynamic Mercury Cycling Mode (D-MCM), as described in Harris et al. (2020), typically uses a scheme with a well-mixed surface sediment layer and an underlying layer, with a water boundary layer. Hence, this conceptual model is currently not adapted to areas of strong erosion since resuspension is not currently included in the formulation at this time.

FIGURE 2. CONCEPTUAL MODEL FOR THE WATER COLUMN AND BED SEDIMENT. THE INACTIVE SEDIMENT LAYER IS WHERE BURIAL TAKES PLACE.

Hence, instead of incorporating the Hg model within the sediment diagenesis module of CE-QUAL-W2, the Hg sediment module would exist "alongside" the sediment diagenesis model and use model predictions from the sediment diagenesis model as needed, in a manner maintaining internal consistency between the behavior and properties of the mercury sediment layer and the diagenesis model.

The Hg module simulates elemental mercury, Hg0, inorganic mercury, HgII, and methylmercury, MeHg, in the water column and HgII and MeHg in the active sediment layer (Figure 3). In the water column, HgO is simulated only in the dissolved phase, while HgII and MeHg are partitioned among particles and two dissolved components: that portion bound to dissolved organic carbon (DOC) and that considered "freely dissolved", or not bound to DOC. Particle types in the water column competing for HgII and MeHg include refractory and labile organic solids (particulate organic matter, POM), multiple types of inorganic solids (based on particle size), multiple types of algae, and multiple types of zooplankton. Some sediment HgII and MeHg can partition into lower trophic level benthic organisms, but that feature may be added at a later time. This assumes in the interim that mercury allocated to benthic organisms does not have an appreciable effect on concentrations on sediment solids or porewater. Even though HgII and MeHg partitioning can have fast and slow exchanging components, this model is using fast exchange or equilibrium, instantaneous exchange. The slow component, if included would include adsorption and desorption kinetics and would be applied to non-living solids (organic and inorganic) and possibly DOC-bound HgII and MeHg. Besides adding more complexity and model coefficients to the algorithm, using non-equilibrium partitioning would increase the number of state variables in the model. These new state variables would be the

HgII and MeHg sorbed components of all the solid fractions and dissolved fractions. A summary of a similar model is shown in prior work by Zhong and Johnson (2016).

FIGURE 3. CONCEPTUAL MODEL OF HG BIOGEOCHEMICAL PROCESSES. ZOO SORBED IS ZOOPLANKTON SORBED FRACTION. THE SOLIDS SORBED INCLUDE BOTH INORGANIC SUSPENDED SOLIDS GROUPS AND ORGANIC SOLIDS GROUPS.

### Water Column Processes

As conceptualized in Figure 3, three Hg species in the water column are modeled in CE-QUAL-W2: Hg0, HgII, and MeHg.

- [Hg0], concentration of dissolved elemental Hg in water (ng L<sup>-1</sup>) or (μg m<sup>-3</sup>)
- [HgII], concentration of total (unfiltered) inorganic HgII in water (ng L<sup>-1</sup>)
- [MeHq], concentration of total (unfiltered) MeHg in water (ng L<sup>-1</sup>)

The governing equation for all water column constituents is the laterally averaged 3-D advective-diffusion equation:

$$\frac{\partial B\Phi}{\partial t} + \frac{\partial UB\Phi}{\partial x} + \frac{\partial WB\Phi}{\partial z} - \frac{\partial}{\partial x} \left[ BD_x \frac{\partial \Phi}{\partial x} \right] - \frac{\partial}{\partial z} \left[ BD_z \frac{\partial \Phi}{\partial z} \right] = q_{\Phi}B + S_{\Phi}B$$

where:

 $\Phi$  = laterally averaged Hg constituent concentration,  $\mu g m^{-3}$ 

 $D_x$  = longitudinal temperature and constituent dispersion coefficient, m<sup>2</sup> sec<sup>-1</sup>

D<sub>z</sub> = vertical temperature and constituent dispersion coefficient, m<sup>2</sup> sec<sup>-1</sup>

 $q_{\Phi} = {
m lateral~inflow~or~outflow~mass~flow~rate~of~constituent~per~unit~volume,~\mu g~m^{-3}~sec^{-1}$ 

 $S_{\Phi}$  = laterally averaged source/sink term,  $\mu g m^{-3} sec^{-1}$ .

The CE-QUAL-W2 User Manual (Wells, 2023) describes how the velocity field and dispersion coefficients are computed and solved numerically.

The concentrations of Hg species in the model are expressed in terms of nanograms per volumetric units of liter (ng L<sup>-1</sup>). Dissolved *HgII* and *MeHg* are each grouped into two components, those bound to DOC and those freely dissolved. In addition, *HgII* and *MeHg* are found in multiple solids types: refractory particulate organic matter (RPOM), labile particulate matter (LPOM), inorganic suspended solids groups, algae groups, and zooplankton groups. The model also computes distributed concentrations of total (unfiltered) HgII and MeHg in the water column as derived variables in the CE-QUAL-W2. In the current model application, we have assumed only two inorganic suspended solids groups: fine and coarse, but the current model framework is not limited to only two components.

The *HgII* and *MeHg* components computed in the water column include:

- Hall<sub>d</sub>, concentration of freely dissolved Hall in water(ng L<sup>-1</sup>)
- *HgII<sub>doc</sub>*, concentration of DOC complexed HgII in water (ng L<sup>-1</sup>)
- HgII<sub>totdiss</sub>, total dissolved HgII concentration (DOC-bound plus other) (ng L<sup>-1</sup>)
- Hgll<sub>apt</sub>, total concentration of algae (phytoplankton) adsorbed Hgll in water (ng L<sup>-1</sup>)
- HgII<sub>Lpom</sub>, concentration of labile organic solid adsorbed HgII in water (ng L<sup>-1</sup>)
- Hgll<sub>Rpom</sub>, concentration of refractory organic solid adsorbed Hgll in water (ng L<sup>-1</sup>)
- Hgll<sub>pt</sub>, total concentration of TSS (inorganic and organic solids) adsorbed Hgll in water (ng L<sup>-1</sup>)
- Hgll<sub>pts</sub>, total concentration of TSS (inorganic and organic solids) adsorbed Hgll in water (ng g<sup>-1</sup>)
- MeHg<sub>d</sub>, concentration of dissolved MeHg in water (ng L<sup>-1</sup>)
- MeHg<sub>doc</sub>, concentration of DOC complexed MeHg in water (ng L<sup>-1</sup>)
- MeHg<sub>apt</sub>, total concentration of algae (phytoplankton) adsorbed MeHg in water (ng L<sup>-1</sup>)
- MeHgpom, concentration of organic solid adsorbed MeHg in water (ng L-1)
- *MeHg<sub>pt</sub>*, total concentration of TSS (inorganic and organic solids) adsorbed MeHg in water (ng L<sup>-1</sup>)
- $MeHg_{pts}$ , total concentration of TSS (inorganic and organic solids) adsorbed MeHg in water (ng g<sup>-1</sup>)

The Hg module simulates the following transformation processes among three Hg species in the water column:

Photo-degradation: MeHg → Hg0

Photo-Reduction: HgII → Hg0

• Photo-Oxidation: Hg0 → HgII

Biological methylation: HgII → MeHg

Biological demethylation: MeHg → HgII

Additionally, the model accounts for atmospheric boundary fluxes of HgII and MeHg. These fluxes could include the following processes, even though they are lumped together in the model:

- Wet deposition of MeHg
- Wet deposition of HgII
- Dry deposition of HgII
- Reactive gaseous mercury (RGM) deposition of HgII

### Equilibrium Partitioning and Distribution of HgII and MeHg in the Water Column

HgII and MeHg may be partitioned between the freely dissolved phase and DOC, and the solid adsorbed phases. Solids can be assigned to mineral abiotic solids, detrital (particulate organic matter), or various classes or size categories of solids. Under an equilibrium partitioning, all HgII and MeHg are assumed to be instantly exchangeable between the freely dissolved, DOC complexed, algae (1 to NAL, where NAL is the number of algal groups), organic solids (two groups), and inorganic solids (1 to NSS, where NSS is the number of inorganic suspended solids groups) adsorbed phases. The linear partitioning fractions of HgII and MeHg in the water column are computed as:

$$f_d = \frac{10^6}{R} \tag{1a}$$

$$f_{doc} = \frac{K_{doc}[DOC]}{R} \tag{1b}$$

$$f_{apn} = \frac{K_{apn}[A_{pn}]}{R} \tag{1c}$$

$$f_{pom} = \frac{K_{pom}[POM]}{R} \tag{1d}$$

$$f_{pn} = \frac{K_{pn}[ISS_n]}{R} \tag{1e}$$

$$R = 10^{6} + K_{doc}[DOC] + K_{pom}[POM] + \sum_{n=1}^{NAL} K_{avn}[A_{vn}] + \sum_{n=1}^{N} K_{vn}[ISS_{n}]$$
(1f)

and

$$f_d + f_{doc} + f_{pom} + \sum_{n=1}^{NAL} f_{apn} + \sum_{n=1}^{NSS} f_{pn} = 1$$
 (1g)

where subscript i represents either HgII or MeHg in the water column.

 $f_d$  = fraction of freely dissolved HgII or MeHg in water

 $f_{doc}$  = fraction of DOC complexed HgII or MeHg in water

 $f_{pom}$  = fraction of organic solids adsorbed HgII or MeHg in water

 $f_{apn}$  = fraction of algae (phytoplankton) group n adsorbed HgII or MeHg in water

 $f_{pn}$  = fraction of inorganic solid group n adsorbed HgII or MeHg in water

 $K_{doc}$  = HgII or MeHg equilibrium partition coefficient for DOC in water (L kg<sup>-1</sup>)

 $K_{pom}$  = HgII or MeHg equilibrium partition coefficient for POM in water (L kg<sup>-1</sup>)

 $K_{apn}$  = HgII or MeHg equilibrium partition coefficient for algae (phytoplankton) group n in water (L kg<sup>-1</sup>)

 $K_{pn}$  = HgII or MeHg equilibrium partition coefficient for solid group n in water (L kg<sup>-1</sup>)

DOC = concentration of dissolved organic carbon in water (mg L-1)

 $A_{pn}$  = concentration of algae (phytoplankton) group n in water (mg L<sup>-1</sup>)

POM = concentration of particulate organic matter, including labile and refractory fractions (mg L<sup>-1</sup>)

 $ISS_n$  = concentration of inorganic solid group n in water (mg L<sup>-1</sup>)

NSS = total number of inorganic solid group n in water (mg L<sup>-1</sup>)

*NAL* = total number of algae (phytoplankton) group n in water (mg L<sup>-1</sup>)

Distributed concentrations of *HgII* and *MeHg* for individual phases can be directly calculated from their partitioning fractions and total concentrations in water:

$$HgII_d = f_{d-Holl}[HgII] \tag{2a}$$

$$HgII_{doc} = f_{\text{doc-HgII}}[HgII] \tag{2b}$$

$$HgII_{apt} = \sum_{n=1}^{NAL} f_{ann-Holl}[HgII]$$
 (2c)

$$HgII_{apts} = 10^3 \frac{\sum_{n=1}^{NAL} f_{apn-HgII}[HgII]}{\sum_{n=1}^{NAL} A_{pn}}$$
 (2c)

$$HgII_{pom} = f_{pom-HgII}[HgII]$$
 (2d)

$$HgII_{pt} = \sum_{n=1}^{NSS} f_{\text{tin-Hall}}[HgII]$$
 (2e)

$$HgII_{pts} = 10^{3} \frac{\sum_{n=1}^{NSS} f_{pn-Hgll}[HgII]}{\sum_{n=1}^{NSS} ISS_{n}}$$
 (2f)

and

$$MeHg_d = f_{d-MeHg}[MeHg]$$
 (3a)

$$MeHg_{pom} = f_{pom-MeHg}[MeHg]$$
 (3b)

$$MeHg_{apt} = \sum_{n=1}^{NAL} f_{apn-MeHg}[MeHg]$$
 (3c)

$$MeHg_{apts} = 10^3 \frac{\sum_{n=1}^{NAL} f_{apn-MeHg}[MeHg]}{\sum_{n=1}^{NAL} A_{pn}}$$
 (3c)

$$MeHg_{doc} = f_{doc-MeHg}[MeHg]$$
 (3d)

$$MeHg_{pt} = \sum_{n=1}^{NSS} f_{yn-MeHg}[MeHg]$$
 (3e)

$$MeHg_{pts} = 10^3 \frac{\sum_{n=1}^{NSS} f_{pn-MeHg}[MeHg]}{\sum_{n=1}^{NSS} ISS_n}$$
 (3f)

where

 $HgII_d$  = concentration of freely dissolved HgII in water (ng L<sup>-1</sup>)

 $HgII_{doc}$  = concentration of DOC complexed HgII in water (ng L<sup>-1</sup>)

HgIIpom = concentration of organic solid adsorbed HgII in water (ng L-1)

HgII<sub>apt</sub> = total concentration of algae (phytoplankton) adsorbed HgII in water (ng L<sup>-1</sup>)

 $HgII_{apts}$  = total concentration of algae (phytoplankton) adsorbed HgII in water (ng g<sup>-1</sup>)

 $HgII_{pt}$  = total concentration of inorganic solids adsorbed HgII in water (ng L<sup>-1</sup>)

 $HgII_{pts}$  = total concentration of inorganic solids adsorbed HgII in water (ng g<sup>-1</sup>)

 $MeHq_d$  = concentration of dissolved MeHg in water (ng L<sup>-1</sup>)

 $MeHg_{doc}$  = concentration of DOC complexed MeHg in water (ng L<sup>-1</sup>)

 $MeHg_{pom}$  = concentration of organic solid adsorbed MeHg in water (ng L<sup>-1</sup>)

MeHgapt = total concentration of algae (phytoplankton) adsorbed MeHg in water (ng L-1)

 $MeHg_{apts}$  = total concentration of algae (phytoplankton) adsorbed MeHg in water (ng g<sup>-1</sup>)

 $MeHg_{pt}$  = total concentration of inorganic solids adsorbed MeHg in water (ng L<sup>-1</sup>)

 $MeHg_{pts}$  = total concentration of inorganic solids adsorbed MeHg in water (ng g<sup>-1</sup>)

### Water Column Internal Source/Sink Rate Equations for HgO, HgII, MeHg

Components of the mass balance of Hg species (*HgO*, *HgII* and *MeHg*) for a control volume compartment include: first, changes by physical transport; second, changes by forcing functions to or from the compartment; and third, changes by physical, chemical and biological (or biochemical) processes occurring within the compartment. Physical, chemical and biological (or biogeochemical) processes occurring within the compartment are lumped into internal source and sink kinetic rates and described below.

### Elemental Hg (Hg0):

The following four processes are simulated for *Hg0*:

- Hg0 photo-oxidation
- HgII photo-reduction
- MeHg photo-degradation
- HgO volatilization

Transformations of *HgII* and *MeHg* act on all dissolved HgII and MeHg (DOC-bound and freely dissolved). The internal source and sink rate equation for the concentration of *HgO* in the water column is stated as

$$\frac{d[Hg0]}{dt} = -\underbrace{Hg0 \rightarrow HgII}_{\text{photo-oxidation}} + \underbrace{HgII \rightarrow Hg0}_{\text{photoreduction}} + \underbrace{MeHg \rightarrow Hg0}_{\text{photodegradation}} + \underbrace{\frac{dHg0}{dt}}_{\text{evasion}} \tag{4}$$

Advective and dispersive fluxes within the water column are included as part of the CE-QUAL-W2 hydrodynamic modeling framework.

### 1) Photoreduction (HgII → Hg0)

The photoreduction rate from *HgII* to *Hg0* is computed as:

$$\underbrace{HgII \to Hg0}_{\text{photoreduction}} = K_{reductionPAR} \, \bar{I}_{PAR} \big( f_{\text{d-HgII}} + f_{\text{doc-HgII}} \big) [HgII] \tag{5}$$

where

 $I_{PAR}$  = PAR light intensity in the model layer ( $W/m^2$ )

 $K_{reductionPAR}$  = photoreduction constant for PAR  $(\frac{m^2}{Wd})$  converted to  $m^2$  W<sup>-1</sup>s<sup>-1</sup> internally in the model

The light in the layer (K) and segment (I) is computed from the following for each layer:

$$\bar{I}_{PAR} = I_{in} - I_{out}$$

where

$$I_{in} = I(z_1) = (1 - \beta)\varphi_{sn}e^{-\eta z_1}$$

$$I_{out} = I(z_2) = (1 - \beta)\varphi_{sn}e^{-\eta z_2}$$

β: fraction of short-wave solar absorbed on surface (0.45 typical value) which is about the PAR fraction of the solar radiation

 $\varphi_{sn}$ : net short wave solar at water surface including effect of shading and reflection and clouds (W/m²)

η: light extinction coefficient (1/m)

z<sub>1</sub>: Depth from surface of top of layer K (m)

z<sub>2</sub>: depth from surface to bottom of layer K (m)

### 2) Photo-oxidation (Hg0 → HgII)

Calculate a target DGM (dissolved gaseous Hg) ratio based on DOC and pH:

$$DGM_{ratio\ target} = k_oxid_1 DOC^{k_oxid_2} pH^{k_oxid_3}$$

Calculate the current DGM ratio in the simulation:

$$DGM_{ratio} = \frac{[Hg0]}{(f_{d-Hg|l} + f_{doc-Hg|l})[HgII]}$$

The photo-oxidation rate from *Hg0* to *HgII* is computed as a function of the reduction rate:

$$k_{oxid\_red} = \frac{DGM_{ratio}}{DGM_{ratio\_target}}$$

$$\underbrace{Hg0 \to HgII}_{\text{photo-oxidation}} = k_{oxid\_red} * \underbrace{HgII \to Hg0}_{\text{photoreduction}} \text{,} \qquad DGM_{ratio} > DGM_{ratio\_target}$$

$$\underbrace{Hg0 \rightarrow HgII}_{locatio} = 0, \qquad DGM_{ratio} \leq DGM_{ratio\_target}$$

Alternatively, oxidation could scale with the DGM ratio rather than shut off when the DGM ratio is below the target:

Use the  $k_{oxid}$  ratio where the target DGM<sub>ratio</sub> exceeds the simulated DGM<sub>ratio</sub>:

$$\underbrace{Hg0 \rightarrow HgII}_{\text{photo-oxidation}} = k_{oxid\_red} * \underbrace{HgII \rightarrow Hg0}_{\text{photoreduction}}, \quad DGM_{ratio} \leq DGM_{ratio\_target} \text{ (6)}$$

### 3) Photodegradation (MeHg → Hg0)

The degradation rate from MeHq into HqO is computed as:

$$\underbrace{MeHg \to Hg0}_{\text{photodegradation}} = K_{photoDegPAR} \, \bar{I}_{PAR} \, \left( f_{d\text{-MeHg}} + f_{doc\text{-MeHg}} \right) [MeHg] \tag{7}$$

where

 $K_{photoDegPAR} = \text{MeHg photodegedation rate constant for PAR } (m^2/(Wd))$  converted to  $m^2 W^{-1}s^{-1}$  internally in the model

### 4) Volatilization of Hg0

The volatilization rate of *HgO* across the air-water interface is computed as (Mills et al., 1982):

$$\frac{dHg0}{dt} = k_{Hg0} \frac{\left( [Hg0] - \frac{[Hg0]_{atm}}{H_{Hg0}} \right)}{h_{cell}}$$
(8)

where 
$$k_{Hg0} = \frac{1.0}{\frac{1.0}{k_{Hg0\_wat}} + \frac{1.0}{k_{Hg0\_air} H_{Hg0}}}$$

$$k_{Hg0\_wat} = 0.632k_a$$

$$k_{Hg0\_air} = 91.949u_w$$

The HgO volatilization rate is based on the 2-resistance model of gas transfer where both the liquid and gas layer control the overall transfer rate.

 $H_{Hq0}$  is a function of water temperature calculated using the equation of Sanemasa (1975).

$$H_{Hg0}(T) = 10^{\frac{-1078}{T_{wk}} - \log(T_{wk}) + 5.592}$$
(9)

where

$$DGM_{ratio\_target} = \text{calculated target ratio for } \left( \frac{[\text{Hg0}]}{[\text{HgII}]_{\text{dissolved}}} \right) \ (dimensionless)$$

 $h_{cell}$  = surface layer depth or thickness (m)

 $[Hg0]_{atm}$  = atmospheric concentration of Hg0 ( $\mu g/m^3$ )

 $H_{Hg0}$  = Henry's law constant for Hg0 (dimensionless)

 $K_{oxid_1}$  = Constant in eqn to assign target DGMratio

 $K_{oxid\ 2}$  = Constant in eqn to assign target DGMratio (dimensionless)

 $K_{oxid\ 3}$  = Constant in eqn to assign target DGM ratio (dimensionless)

 $k_a$  = oxygen reaeration rate (m d<sup>-1</sup>) computed from CE-QUAL-W2 model

 $k_{Hq0} = overall \, Hg0 \, gas \, transfer \, rate \, (m \, d^{-1})$ 

 $k_{Hg0\_water}$  = liquid film Hg0 gas transfer rate (m d<sup>-1</sup>)

 $k_{Hg0\_air} = gas film Hg0$  gas transfer rate (m d<sup>-1</sup>)

 $u_w = \text{wind speed (m s}^{-1})$ 

 $T_{wk}$  = water temperature in  ${}^{\circ}K$ 

Inorganic Hg (HgII)

The following six processes are simulated for the water column *HgII*:

- Hg0 photo-oxidation
- Biological demethylation
- Photo-reduction
- Methylation
- Settling of sorbed fractions
- Diffusion across the sediment-water interface

Partitioning of HgII and MeHg onto solids in the water column will result in associated settling fluxes as solids settle. Dissolved phases of HgII and MeHg on the streambed also exchange across the sediment-water interface through diffusion process. The internal source and sink rate equation for the total concentration of *HgII* in the water column is stated as

$$\frac{d[HgII]}{dt} = -\underbrace{HgII \rightarrow Hg0}_{\text{photoreduction}} + \underbrace{Hg0 \rightarrow HgII}_{\text{photo-oxidation}} - \underbrace{HgII \rightarrow MeHg}_{\text{methylation}} + \underbrace{MeHg \rightarrow HgII}_{\text{demethyation}} - \underbrace{HgII \rightarrow Bed}_{\text{settling}} + \underbrace{HgII \leftrightarrow Bed}_{\text{diffusion}} + S_{atm\_dep\_HgII}$$
(10)

Where S<sub>atm\_dep\_HgII</sub> is the atmospheric deposition source term for the surface layer only. Advective and dispersive fluxes in x and z within the water column are part of the CE-QUAL-W2 hydrodynamic modeling framework. Photo-oxidation is described in the section on elemental Hg (Hg0).

### 1) Methylation (HgII → MeHg)

There are 2 options to compute methylation: one based on carbon turnover rate and another decoupled from carbon turnover.

### Carbon Turnover Rate Method

The methylation rate from *HgII* to *MeHg* is computed from the concentration of dissolved and DOC complexed phases of HgII in the water column.

$$\underbrace{HgII \rightarrow MeHg}_{\text{meth-wat}} = \left(K_{meth-wat}f_{\text{d-HgII}} + K_{meth-doc}f_{\text{doc-HgII}}\right)[JOC][HgII] \tag{11}$$

where JOC is the anoxic fraction of the total C turnover rate in units of g  $C/m^3/s$ . In the Ce-QUAL-W2 model this is computed from the following equation:

$$JOC = (LPOMCD + LRPOMCD + RPOMCD + LDOMCD + LRDOMCD + RDOMCD) ANOX \frac{KDO}{KDO + O2}$$

where

 $LPOMCD = \mu_{LPOM} C_{LPOMC}$  rate of decay of LPOM C in g C/m³/s

 $LRPOMCD = \mu_{LRPOM}C_{LPOMC}$  rate of decay of labile to refractory POM C in g C/m<sup>3</sup>/s

 $RPOMCD = \mu_{RPOM}C_{RPOMC}$  rate of decay of RPOM C in g C/m<sup>3</sup>/s

 $LDOMCD = \mu_{LDOM}C_{LDOMC}$  rate of decay of LDOM C in g C/m<sup>3</sup>/s

 $RDOMCD = \mu_{RDOM}C_{RDOMC}$  rate of decay of RDOM C in g C/m<sup>3</sup>/s

 $LRDOMCD = \mu_{LRDOM}C_{LDOMC}$  rate of decay of labile to refractory DOM C in g C/m<sup>3</sup>/s

 $\mu_{LPOM}$ : decay rate for LPOM, corrected for temperature in s<sup>-1</sup>

 $\mu_{LRPOM}$ : decay rate for LPOM to RPOM, corrected for temperature in s<sup>-1</sup>

 $\mu_{RPOM}$ : decay rate for RPOM, corrected for temperature in s<sup>-1</sup>

 $\mu_{LDOM}$ : decay rate for LDOM, corrected for temperature in s<sup>-1</sup>

 $\mu_{RDOM}$ : decay rate for RDOM, corrected for temperature in s<sup>-1</sup>

 $\mu_{LRDOM}$ : decay rate for LDOM to RDOM, corrected for temperature in s<sup>-1</sup>

C<sub>RPOMC</sub>: concentration of refractory particulate organic matter C in g/m<sup>3</sup>

C<sub>LPOMC</sub>: concentration of labile particulate organic matter C in g/m<sup>3</sup>

C<sub>RDOMC</sub>: concentration of refractory dissolved organic matter C in g/m<sup>3</sup>

C<sub>LDOMC</sub>: concentration of labile dissolved organic matter C in g/m<sup>3</sup>

ANOX: fraction of anoxic to oxic carbon (or organic matter) decomposition between 0 and 1

KDO: dissolved oxygen concentration half-saturation limit in g/m<sup>3</sup>

O2: concentration of dissolved oxygen in g/m<sup>3</sup>

$$K_{meth-wat}$$
 = methylation rate constant for HgII dissolved  $\left(\frac{m^3}{g c}\right)$ 

$$K_{meth-doc}$$
 = methylation rate constant for HgII bound to DOC  $\left(\frac{m^3}{gc}\right)$ 

Note that ANOX multiplied by the oxic organic matter decay rates is the anoxic portion of the organic matter decay. Usually, ANOX is much less than 1. The term  $\frac{KDO}{KDO+O2}$  provides a smooth transition from oxic to anoxic conditions and is equal to 1 when there is no dissolved oxygen. KDO is the DO concentration when anoxic metabolism is 50% of its maximum (maximum is when DO=0 mg/l).

### Methylation Not Based on Carbon Turnover

Another option in the CE-QUAL-W2 model is to compute methylation and demethylation as only dependent on degree of anoxia and a rate constant that is a function of temperature. In this case methylation can be computed as

$$\underbrace{HgII \rightarrow MeHg}_{\text{meth-wat}} = \left( K_{meth-wat} f_{d-Hg|I} + K_{meth-doc} f_{doc-Hg|I} \right) \frac{KDO}{KDO + O2} [HgII] \tag{12}$$

where

 $K_{meth-wat} = \text{methylation rate constant for HgII dissolved } \left(\frac{1}{s}\right) \text{ adjusted by temperature.}$ 

$$K_{meth-doc} = \text{methylation rate constant for HgII bound to DOC}\left(\frac{1}{s}\right)$$
 adjusted by temperature.

Earlier the temperature dependence was based on carbon turnover rate dependencies, but in this approach the model user must specify the temperature dependence for the rate constants. An Arrhenius formulation is used to be compatible with earlier Hg studies. Hence, for demethylation the formula for adjusting temperature of the coefficient is

 $k_T=k_{20}\theta^{T-20}$  where  $k_T$  is the kinetic coefficient adjusted to a temperature T,  $k_{20}$  is the coefficient at 20°C, and theta is an empirical parameter. In the model the value of Q10 is specified, which is  $Q10=\theta^{20-10}$  which allows the computation of theta as  $\theta=O10^{1/(20-10)}$ .

### 2) Demethylation (MeHg → HgII)

### Carbon turnover method

The demethylation rate from *MeHg* to *HgII* is computed from the concentration of dissolved and DOC complexed phases of MeHg in the water column.

$$\underbrace{MeHg \rightarrow HgII}_{\text{demeth-wat}} = \left( K_{demeth-wat} f_{\text{d-MeHg}} + K_{demeth-doc} f_{\text{doc-MeHg}} \right) [JPOC] [MeHg] \quad (13)$$

where

 $K_{demeth-wat}$  = demethylation rate constant for dissolved MeHg  $\left(\frac{m^3}{qC}\right)$ 

 $K_{demeth-doc}$  = demethylation rate constant for MeHg bound to DOC  $\left(\frac{m^3}{g c}\right)$ 

### Demethylation Not Based on Carbon Turnover

Another option in CE-QUAL-W2 is to compute demethylation as a function of the degree of anoxia and demethylatyion rates adjusted by temperature such as

$$\underbrace{\underline{\mathit{MeHg}} \rightarrow \mathit{HgII}}_{\text{demeth-wat}} = \left( K_{demeth-wat} f_{d\text{-MeHg}} + K_{demeth-doc} f_{\text{doc-MeHg}} \right) \frac{\mathit{KDO}}{\mathit{KDO} + \mathit{O2}} [\mathit{MeHg}] \tag{14}$$

where

 $K_{demeth-wat} = \text{demethylation rate constant for dissolved MeHg}\left(\frac{1}{s}\right)$  adjusted by temperature

 $K_{demeth-doc} = \text{demethylation rate constant for MeHg bound to DOC} \left(\frac{1}{s}\right)$  adjusted by temperature

The temperature adjustment is similar to the methylation temperature rate adjustment when it is not based on C turnover.

### 3) Diffusion across the sediment-water interface

Dissolved Hg species in the bed sediment can transfer across the sediment-water interface, or vice versa. The total porewater concentration of HgII is the sum of the freely-dissolved and DOC-complexed HgII. Therefore, the diffusion mass transfer of HgII across the sediment-water interface is computed as:

$$\underbrace{HgII \leftrightarrow Bed}_{\text{diffusion}} = \frac{v_m}{h} \left[ \left( f_{\text{d-HgII2}} + f_{\text{doc-HgII2}} \right) \frac{HgII_2}{\varphi} - \left( f_{\text{d-HgII}} + f_{\text{doc-HgII}} \right) HgII \right]$$
(15)

where

 $v_m$ : sediment-water transfer coefficient (velocity) (m s<sup>-1</sup>).

### h: layer thickness.

The mass transfer velocity  $(v_m)$  of HgII and MeHg across the sediment-water interface can be either a user specified parameter (constant over time and space) or determined from the sediment diagenesis model which computes the diffusion velocity from the water to the aerobic layer and from the aerobic to the anaerobic layer. To compute an average velocity from the bed to the water column, an overall velocity based on resistance model in series to compute the average velocity. The model user can scale that velocity for use in the Hg model. From the sediment diagenesis model, we use the sediment transfer velocity from the aerobic layer to the water, the porewater diffusion velocity (from anaerobic layer to aerobic layer) and the particle mixing velocity (accounting for bioturbation) to compute an average sediment-water transfer velocity.

Hence,  $v_m$  is computed from the following equation:

$$\frac{1}{v_m} = \frac{1}{v_{KL12} + v_{W12}} + \frac{1}{v_S}$$

• Where  $v_m$  is the Hg transfer velocity in m/d,  $v_{KL12}$  is the porewater diffusion velocity between layer 1 and 2 in m/d,  $v_{W12}$  is the particle mixing velocity between layer 1 and 2 in m/d, and  $v_S$  is the transfer velocity between the water and layer 1 as shown in Figure 4.

FIGURE 4. COMPARISON OF DIFFUSION VELOCITIES IN THE SEDIMENT DIAGENESIS MODEL AND THAT IN THE HG SEDIMENT MODEL.

As an example of the transfer velocities computed by the CE-QUAL-W2 model, Figure 5 shows the sediment diagenesis components for one segment in Brownlee reservoir showing the rate limiting flux is the transfer from the anaerobic to the aerobic layer (KL12).

FIGURE 5. VARIATION OF SEDIMENT DIAGENESIS TRANSFER VELOCITIES AT A MODEL SEGMENT IN BROWNLEE RESERVOIR, ID/OR FOR THE BOTTOM LAYER.

Using these velocities from Figure 5, the Hg transfer velocity assuming 100% of the sediment diagenesis transfer velocity is shown for a couple model segments bottom layers in Brownlee Reservoir over a 4-year period in Figure 6.

FIGURE 6. VARIATION OF HG SEDIMENT TRANSFER VELOCITIES AT A COUPLE SEGMENTS AT THE BOTTOM LAYERS OVER MULTIPLE YEARS SHOWING VARIATION IN TEMPERATURE AND SEDIMENT CONDITIONS.

### 4) Settling

Settling of algae, organic and inorganic suspended solids removes adsorbed Hg species in proportion to their bulk concentrations. The settling term of sorbed Hg for the surface layer (kt) is computed as

$$\underbrace{HgII \rightarrow Bed}_{settling} = -\frac{(v_{pom}f_{pom-Hg} + \sum_{n=1}^{NAL} v_{apn}f_{apn-Hg} + \sum_{n=1}^{NSS} v_{spn}f_{pn-Hg})HgII(kt)}{h(kt)}$$
(16a)

Where h(kt) is the surface layer thickness (m), and (kt) is the array element at the surface.

The settling term of sorbed HgII for remaining layers below the surface layer for each layer k is computed as

$$\underbrace{HgII \rightarrow Bed}_{settling} = \frac{\left(v_{pom}f_{pom-Hg} + \sum_{n=1}^{NAL} v_{apn}f_{apn-Hg} + \sum_{n=1}^{NSS} v_{spn}f_{pn-Hg}\right)(HgII(k-1) - HgII(k))}{h(k)} \tag{16b}$$

where

 $v_{pom}$  = settling velocity of POM (m d<sup>-1</sup>)

 $v_{apn}$  = settling velocity of algae group n (m d<sup>-1</sup>)

 $v_{spn}$  = settling velocity of inorganic solid group n (m d<sup>-1</sup>).

### Methylmercury (MeHg):

The following six processes are simulated for the water column MeHg:

- Methylation
- Photodegradation
- Volatilization
- Biological Demethylation
- Settling of sorbed fractions
- Diffusion across the sediment-water interface

The internal source and sink rate equation for the total concentration of *MeHg* in the water column is stated as

$$\frac{d[MeHg]}{dt} = -\underbrace{MeHg \to Hg0}_{\text{photodegradation}} - \underbrace{MeHg \to HgII}_{\text{demethyation}} + \underbrace{HgII \to MeHg}_{\text{methylation}} - \underbrace{MeHg \to Bed}_{\text{settling}} + \underbrace{MeHg \leftrightarrow Bed}_{\text{diffusion}} + S_{atm\_dep\_MeHg}$$
(17)

where S<sub>atm\_dep\_MeHg</sub> is the atmospheric deposition source term for the surface layer only. Advective and dispersive fluxes in x and z within the water column are part of the CE-QUAL-W2 hydrodynamic modeling framework. Photodegradation is described in the section on elemental Hg. Methylation and demethylation are described in the section on inorganic Hg (HgII).

1) Diffusion across the sediment-water interface

Sediment-water flux of MeHg is computed as:

$$\underbrace{\textit{MeHg} \leftrightarrow \textit{Bed}}_{\textit{diffusion}} = \frac{v_m}{h} \left[ \left( f_{\textit{d-MeHg2}} + f_{\textit{doc-MeHg2}} \right) \frac{\textit{MeHg}_2}{\varphi} - \left( f_{\textit{d-MeHg}} + f_{\textit{doc-MeHg}} \right) \textit{MeHg} \right] \tag{18}$$

### 2) Settling

The settling term of a sorbed Hg for a surface layer of height h(kt) is computed as:

$$\underbrace{MeHg \rightarrow Bed}_{settling} = -\frac{(v_{pom}f_{pom-Hg} + \sum_{n=1}^{NAL} v_{apn}f_{apn-Hg} + \sum_{n=1}^{NSS} v_{spn}f_{pn-Hg})MeHg(kt)}{h(kt)}$$
(19)

The settling term of a sorbed Hg for remaining layers of height h(k) below the surface layer is computed as:

$$\underbrace{MeHg \to Bed}_{\substack{Settling}} = \underbrace{\frac{\left(v_{pom}f_{pom-Hg} + \sum_{n=1}^{NAL}v_{apn}f_{apn-Hg} + \sum_{n=1}^{NSS}v_{spn}f_{pn-Hg}\right)\left(MeHg(k-1) - MeHg(k)\right)}_{h(k)}$$
(19)

### **Active Sediment Layer Processes**

An active Hg sediment layer and its relationship with the corresponding sediment diagenesis are shown in Figure 7. Two Hg species in the active sediment layer are modeled in W2: *HgII* and *MeHg*.

- [Hgll2], concentration of total inorganic Hg with respect to a unit volume of total sediments (ng L<sup>-1</sup>)
- [MeHg2], concentration of total MeHg with respect to a unit volume of total sediments (ng L<sup>-1</sup>)

Currently, information from the sediment diagenesis model includes temperature, sediment diffusion velocity  $(v_m)$ , organic solids in the sediment layer, and C turnover rate in the sediments for computation of methylation in the sediments.

FIGURE 7. HG SEDIMENT LAYER DYNAMICS. FOR THE CURRENT MODEL RESUSPENSION IS NOT CONSIDERED.

Initial conditions of the state variables (HgII and MeHg) in ng/l, as well as sediment inorganic suspended solids in mg/l, were required for the active sediment layer.

*HgII* and *MeHg* can exist in the freely dissolved phase, DOC complexed phase, and attached to organic and inorganic solids in the sediment layer. The model will compute the following derived variables from the concentrations of total HgII and MeHg in sediment.

- HgII2<sub>d</sub>, concentration of freely dissolved HgII in porewater(ng L<sup>-1</sup>)
- Hgll2<sub>doc</sub>, concentration of DOC complexed Hgll in porewater (ng L<sup>-1</sup>)
- HgII2<sub>pom</sub>, concentration of organic solid adsorbed HgII in sediment (ng L<sup>-1</sup>)
- HgII2<sub>pt</sub>, total concentration of inorganic solids adsorbed HgII in sediment (ng L<sup>-1</sup>)
- HgII2<sub>pts</sub>, total concentration of inorganic solids adsorbed HgII in sediment (ng g<sup>-1</sup>)
- MeHq2<sub>d</sub>, concentration of dissolved MeHg in porewater (ng L<sup>-1</sup>)
- MeHg2<sub>doc</sub>, concentration of DOC complexed MeHg in porewater (ng L<sup>-1</sup>)
- MeHg2pom, concentration of organic solid adsorbed MeHg in sediment (ng L<sup>-1</sup>)
- MeHg2<sub>pt</sub>, total concentration of inorganic solids adsorbed MeHg in sediment (ng L<sup>-1</sup>)
- MeHg2<sub>pts</sub>, total concentration of inorganic solids adsorbed MeHg in sediment (ng g<sup>-1</sup>)

The total concentrations of *HgII* and *MeHg* within the sediment layer are computed in terms of mass per unit volume of water plus solids (ng L<sup>-1</sup>). The following five processes are simulated for *HgII* and *MeHg* in the active sediment layer:

- Biological methylation
- Biological demethylation
- Settling of each non-living solid type
- Diffusion across the sediment-water interface
- Sediment deep burial (or erosion if settling is less than the sum of resuspension and decomposition.

Currently, resuspension of bed sediment is not included in the model.

# 1.2.1 Equilibrium partitioning and distribution of HgII and MeHg in the active sediment layer

Equilibrium partitioning of Hg species is handled in the same manner in the sediment layer as in the water column. The fractions associated with the dissolved phase in pore water, DOC complexed, and the solids adsorbed phases, are computed with considering the water content or porosity,  $\varphi$ .

$$f_{d2} = \frac{10^6 \varphi}{R_2} \tag{20a}$$

$$f_{doc2} = \frac{K_{doc2}\varphi \cdot [DOC2]}{R_2} \tag{20b}$$

$$f_{pom2} = \frac{K_{pom2}[POM2]}{R_2} \tag{20c}$$

$$f_{pn2} = \frac{K_{pn2}[ISS2_n]}{R_2}$$
 (20d)

$$R_2 = 10^6 \varphi + K_{doc2} \varphi [DOC2] + K_{pom2} [POM2] + \sum_{n=1}^{NSS} K_{pn2} [ISS2_n]$$
 (20e)

and

$$f_{d2} + f_{doc2} + f_{pom2} + \sum_{n=1}^{NSS} f_{pn2} = 1$$
 (20f)

where

fd2 = Fraction of dissolved HgII or MeHg in sediment

fdoc2 = Fraction of DOC complexed HgII or MeHg in sediment

fpn2 = Fraction of solids adsorbed HgII or MeHg in sediment

Kdoc2 = HgII or MeHg equilibrium partition coefficient for sediment DOC (L kg<sup>-1</sup>)

Kpom2 = HgII or MeHg equilibrium partition coefficient for sediment POM (L kg<sup>-1</sup>)

Kpn2 = HgII or MeHg equilibrium partition coefficient for sediment solids (L kg<sup>-1</sup>)

DOC2 = Sediment dissolved organic carbon in pore water (mg L<sup>-1</sup>)

POM2 = Concentration of sediment POM (mg L<sup>-1</sup>)

ISS2<sub>n</sub> = Concentration of sediment solid "n" (mg L<sup>-1</sup>)

Dissolved and DOC complexed concentrations of *HgII* and *MeHg* in the sediment layer are calculated based on their mass relative to the total volume of solids and water. The porosity corrected concentrations in pore water are also computed. The multi-phase concentrations of *HgII* and *MeHg* in the sediment layer are computed as:

$$HgII2_d = f_{d-Holl2}[HgII2] \tag{21a}$$

$$HgII2_{doc} = f_{doc-Holl2}[HgII2] \tag{21b}$$

$$HgII2_{nom} = f_{nom-Holi2}[HgII2] \tag{21b}$$

$$HgII2_{pt} = \sum_{n=1}^{NSS} f_{pn-HgII2}[HgII2]$$
 (21c)

$$HgII2_{pts} = 10^{3} \frac{\sum_{n=1}^{NSS} f_{pn-HglII}[HgII2]}{\sum_{n=1}^{NSS} [ISS2_{n}]}$$
(21d)

 $HgII2_d$  and  $HgII2_{doc}$  are computed based on the mass in the dissolved phase and DOC complexed phase per the sediment total volume. These concentrations are expressed based on the sediment pore water volume as:

$$HgII2_{dp} = \frac{HgII2_d}{\varphi} \tag{21e}$$

$$HgII2_{docp} = \frac{HgII2_{doc}}{\varphi} \tag{21f}$$

and

$$MeHg2_d = f_{d-MeHg2}[MeHg2]$$
 (22a)

$$MeHg2_{doc} = f_{doc-MeHg2}[MeHg2]$$
 (22b)

$$MeHg2_{pom} = f_{pom-MeHg2}[MeHg2]$$
 (22b)

$$MeHg2_{pt} = \sum_{n=1}^{NSS} f_{yn-MeHg2}[MeHg2]$$
 (22c)

$$MeHg2_{pts} = 10^{3} \frac{\sum_{n=1}^{NSS} f_{pn-MeHg2}[MeHg2]}{\sum_{n=1}^{NSS}[ISS_{n2}]}$$
(22d)

Concentrations of  $MeHg2_d$ ,  $MeHg2_{doc}$  are expressed based on the sediment pore water volume as:

$$MeHg2_{dp} = \frac{MeHg2_d}{\varphi}$$
 (22e)

$$MeHg2_{docp} = \frac{MeHg2_{doc}}{\varphi}$$
 (22f)

Sediment Layer Internal Source and Sink Rate Equations for HgII, MeHg Inorganic Hg (HgII)

The internal source and sink rate equation for the total concentration of *HgII* in the sediment layer is stated as

$$\frac{d[HgII2]}{dt} = \underbrace{V_{S} \frac{dHgII}{dz}}_{deposition} + \underbrace{MeHg2 \rightarrow HgII2}_{demethyation} - \underbrace{HgII2 \rightarrow MeHg2}_{methylation} - \underbrace{HgII \leftrightarrow HgII2}_{diffusion} - \underbrace{V_{b} \frac{dHgII2}{dz}}_{burial}$$
(23)

### 1) Methylation rate

As in the water column, the methylation rate in the sediments can be based on the rate of anoxic carbon turnover or not.

### **Carbon Turnover Rate Method**

$$\underbrace{HgII2 \rightarrow MeHg2}_{\text{methylation}} = \left( k_{meth_{sed}} f_{\text{d-HgII2}} + k_{meth_{sdoc-sed}} f_{\text{doc-HgII2}} \right) [JOC2] [HgII2]$$

$$(24a)$$

JOC2 is the organic C turnover rate in  $g/m^3/s$  in the sediments. This is computed as follows from the sediment diagenesis model:

$$JOC2 = \mu_{SD\_POC1} \theta_{POC1}^{(T_{sed}-20)} C_{SD\_POC1} + \mu_{SD\_POC2} \theta_{POC2}^{(T_{sed}-20)} C_{SD\_POC2}$$

where

 $\mu_{SD\_POC1}$ : first order sediment decay rate of labile particulate organic C (POC1, also termed POCG1 in sediment diagenesis model), 1/s, at 20°C

T<sub>sed</sub>: sediment diagenesis temperature in anaerobic layer of sediment diagenesis model, °C

 $\Theta_{POC1}$ : Arrhenius temperature correction factor for POC1

C<sub>SD POC1</sub>: concentration in the sediment diagenesis model of labile particulate organic C, g/m<sup>3</sup>

 $\mu_{SD\_POC2}$ : first order sediment decay rate of refractory particulate organic C (POC2, also termed POCG2 in sediment diagenesis model), 1/s, at 20°C

 $\Theta_{POC2}$ : Arrhenius temperature correction factor for POC2

C<sub>SD\_POC2</sub>: concentration in the sediment diagenesis model of refractory particulate organic C, g/m<sup>3</sup>

 $K_{meth-sed} = sediment \text{ methylation rate constant for HgII dissolved } \left(\frac{m^3}{g c}\right)$ 

 $K_{meth-sdoc-sed} = sediment$  methylation rate constant for HgII bound to DOC  $\left(\frac{m^3}{g \ C}\right)$ 

If the sediment diagenesis model is not used, the model uses the C turnover rate from the first order sediment model as

$$JOC2 = \mu_{Sed1}C_{C-sediment}$$

where

 $\mu_{Sed1}$ : first order sediment decay rate corrected by temperature, 1/s

C<sub>C-sediment</sub>: C concentration in the first order sediment model, g/m<sup>3</sup>

Methylation Not Based on Carbon Turnover

$$\underbrace{HgII2 \rightarrow MeHg2}_{\text{methylation}} = \left( k_{meth_{sed}} f_{\text{d-Hg|I2}} + k_{meth_{sdoc-sed}} f_{\text{doc-Hg|I2}} \right) [HgII2] \tag{24b}$$

where

 $K_{meth-sed} = sediment$  methylation rate constant for HgII dissolved  $\left(\frac{1}{s}\right)$  adjusted by temperature.

 $K_{meth-sdoc-sed} =$ 

sediment methylation rate constant for HgII bound to DOC  $\left(\frac{1}{s}\right)$  adjusted by temperature.

Earlier the temperature dependence was based on carbon turnover rate dependencies, but in this approach the model user must specify the temperature dependence for the rate constants. An Arrhenius formulation is used to be compatible with earlier Hg studies. Hence, for demethylation the formula for adjusting temperature of the coefficient is the same as that for the water column, i.e.,  $k_T = k_{20} \theta^{T-20}$ .

### 2) Demethylation rate

If methylation/demethylation are based on C turnover the equation used is

$$\underbrace{MeHg2 \rightarrow HgII2}_{\text{demeth-sed}} = \left(K_{demeth-sed}f_{\text{d-MeHg}} + K_{demeth-sdoc-sed}f_{\text{doc-MeHg}}\right)[JOC2][MeHg2]$$
(25a)

If not, then the equation used is

$$\underbrace{MeHg2 \rightarrow HgII2}_{\text{demeth-sed}} = \left(K_{demeth-sed}f_{\text{d-MeHg}} + K_{demeth-sdoc-sed}f_{\text{doc-MeHg}}\right)[MeHg2] \tag{25b}$$

where

 $K_{demeth-sed} = sediment\ de$ emethylation rate constant for HgII dissolved  $\left(\frac{1}{s}\right)$  adjusted by temperature.

 $K_{demeth-sdoc-sed} =$ 

sediment demethylation rate constant for HgII bound to DOC  $\left(\frac{1}{s}\right)$  adjusted by temperature.

The temperature adjustment is similar to the methylation temperature rate adjustment when it is not based on C turnover.

3) Diffusion rate across the sediment-water surface

$$\underbrace{HgII \leftrightarrow HgII2}_{diffusion} = \frac{v_m}{h^2} \left[ \left( f_{d-Hg|I2} + f_{doc-Hg|I2} \right) \frac{HgII2}{\varphi} - \left( f_{d-Hg|I} + f_{doc-Hg|I} \right) HgII \right] \tag{26}$$

4) Sediment burial rate

$$\frac{dHgII2}{dz} = \frac{1}{h2} v_b \left( f_{\text{pom-HgII2}} + \sum_{n=1}^{NSS} f_{\text{pn-HgII2}} \right) HgII2$$
(27)

Methylmercury (MeHg):

The total sediment concentration of *MeHg* in the active layer is directly computed through solving the following mass balance equation.

$$\frac{d[\textit{MeHg2}]}{dt} = \underbrace{V_s \frac{d\textit{MeHg2}}{dz}}_{\substack{\textit{deposition}}} + \underbrace{HgII2 \rightarrow \textit{MeHg2}}_{\substack{\textit{methylation}}} - \underbrace{\textit{MeHg2} \rightarrow \textit{HgII2}}_{\substack{\textit{demethyation}}} - \underbrace{}$$

$$\underbrace{MeHg \leftrightarrow MeHg2}_{diffusion} - \underbrace{V_b \frac{dMeHg2}{dz}}_{burial}$$
(28)

1) Diffusion rate across the sediment-water surface

$$\underbrace{MeHg \leftrightarrow MeHg2}_{diffusion} = \frac{v_m}{h^2} \left[ \left( f_{d-MeHg^2} + f_{doc-MeHg^2} \right) \frac{MeHg^2}{\varphi} - \left( f_{d-MeHg} + f_{doc-MeHg} \right) MeHg \right] \tag{29}$$

2) Sediment burial rate

$$\frac{dMeHg2}{dz} = \frac{1}{h2} v_b \left( f_{pom-MeHg2} + \sum_{n=1}^{NSS} f_{pn-MeHg2} \right) MeHg2$$
(30)

where

 $k_{meth \ sed} = \text{methylation rate constant} \quad (m^3/g/s)$ 

 $k_{demeth\_sed}$  = biological demethylation rate constant  $(m^3/g/s)$ 

$$V_s = \text{settling rate } (m/s)$$

 $V_b = burial \operatorname{rate}(m/s)$ 

### **Burial Velocity in Sediment Model**

The model user can choose a fixed burial velocity or have it computed internally based on a mass balance of solids entering the sediment layer to those leaving the sediment layer. The internal computation makes the sediment layer solids content consistent over time. The internal burial velocity is computed for each sediment layer in cell k assuming no resuspension from

$$v_b(k) = \frac{\sum_n v_{sn} C_{ss-n}(k)}{\sum_n C_{ss-sed-n}(k)}$$

where

 $C_{ss-n}$  = concentration of inorganic solids of group "n" in water (g m<sup>-3</sup>)

 $C_{ss-sed-n}$  = concentration of inorganic solids of group "n" in sediment bed (g m<sup>-3</sup>)

 $v_{sn}$  = settling velocity of solid "n" (m s<sup>-1</sup>)

 $v_b$  = sediment burial velocity (m s<sup>-1</sup>)

This rate of burial is assumed to be close to that of the organic solids.

### Solids in Sediment Layer

The sediment layer consists of both inorganic solids and organic solids (particulate organic matter, POM) settled from the water column. These are used to compute partitioning in the sediment layer.

Inorganic Solids in Sediment Layer

The inorganic solids concentration in the sediment bed of thickness h2 is computed from the following mass balance for inorganic solids group n:

$$\frac{dC_{SS-Sed-n}}{dt} = \frac{v_{Sn}C_{SS-n} - v_bC_{SS-Sed-n}}{h2}$$

Organic Solids in Sediment Layer

The organic solids concentration in the sediment bed is computed from the sediment diagenesis model as follows:

$$C_{POM-sed} = \frac{POCG1 + POCG2 + POCG3}{ORGC}$$

If the sediment diagenesis model is not used it computes it directly from

$$C_{POM-sed} = \frac{SEDC}{ORGC}$$

where

 $C_{POM-sed}$  = concentration of organic solids in sediment bed (gm<sup>-3</sup>)

ORGC = C to organic matter ratio (typically 0.45)

SEDC = first order sediment model sediment C concentration (gm<sup>-3</sup>)

POCG1 = labile particulate organic C concentration from sediment diagenesis model (gm<sup>-3</sup>)

POCG2 = refractory particulate organic C concentration from sediment diagenesis model

(gm<sup>-3</sup>)

POCG3 = inert particulate organic C concentration from sediment diagenesis model (gm<sup>-3</sup>)

Summary of Water Column and Sediment Model Parameters, Output

### Concentrations and Fluxes

Table 1 shows the water column model parameters used in the CE-QUAL-W2 model and the input units of the model. Internally, the model uses seconds rather than days. Table 2 shows the bed sediment model parameters. Table 3 shows the Hg concentrations output by the model, and Table 4 shows the pathway fluxes output by the model.

TABLE 1. WATER COLUMN HG PARAMETERS

Symbol	Description	Units
Hg0		
v <sub>v-Hg0</sub> (T)	Hg0 volatilization velocity	m d <sup>-1</sup>
Hg0₀	Hg0 air concentration	ng L <sup>-1</sup>
$K_{photoOxid}$	Hg0 photo-oxidation rate	d <sup>-1</sup>
$K_{ozid\_1}$	Oxidation rate constant	-
$K_{ozid\_2}$	Oxidation rate constant	-
$K_{ozid\_3}$	Oxidation rate constant	-
HgII		
<b>K</b> doc-HgII	HgII equilibrium partition coefficient for DOC	L kg <sup>-1</sup>
<b>K</b> apn-HgII	HgII equilibrium partition coefficient for algae "n" (1 – NAL)	L kg <sup>-1</sup>
K <sub>pom-HgII</sub>	HgII equilibrium partition coefficient for organic solids	L kg <sup>-1</sup>
<b>K</b> pn-Hgll	HgII equilibrium partition coefficient for inorganic solid "n" (1 – NSS)	L kg <sup>-1</sup>
$f_{pom}$	fraction of instantaneous HgII binding sites on organic solids	-

# Field Data used in the CE-QUAL-W2 Model

Field data in the Hells Canyon Complex was used for both boundary conditions as well as for in-reservoir model-data comparisons. Figure 8 shows the Brownlee model grid and locations of inflows and outflows. Figure 9 shows the Oxbow model grid and locations of inflows and outflows. Figure 10 shows the Hells Canyon model grid and locations of inflows and outflows.

FIGURE 8. BROWNLEE MODEL GRID. WATER BODY (WB) 1, BRANCH (BR) 1: SEGMENTS 2-29; WB2 (BR2): SEGMENTS 32-42; WB3 (BR 3): SEGMENTS 45-66; WB 4 (BR 4): SEGMENTS 69-83; WB 5: BR 5: SEGMENTS 86-202 (AT DAM), BR 6 SEGMENTS 205-233 (POWDER ARM); BR 7: SEGMENTS 236-238 (INLET CHANNEL). SEGMENT SPACING IN MAINSTEM IS 500 M, IN POWDER ARM 503 M, AND IN INLET CHANNEL 60 M. LENGTH OF MAINSTEM IS 96.5 KM.

Figure 9. Oxbow Model Grid. Segment spacing is 357 m. Length of model domain is 18.2 km.

FIGURE 10. HELLS CANYON MODEL GRID. SEGMENT SPACING IS 351 M (EXCEPT FOR 3 SEGMENTS BEFORE THE DAM TO ACCOUNT FOR COFFERDAM). LENGTH OF MAINSTEM IS 39.6 KM.

## Hg Sediment Initial Conditions

Sediment biogeochemical data published by USGS (Marvin-DiPasquale, et al., 2020) was used to develop some of the parameters for the mercury module for the three reservoirs: initial sediment porewater concentrations of HgII and MeHg. Table 5 lists the average values of shallow sediment (0-5 cm) pore water parameters during the sampling period of 2016-2017 for various river miles. River mile 248 corresponds to HeIIs Canyon Reservoir, and river miles 286-318 correspond to Brownlee Reservoir. HgII was estimated by subtracting the average MeHg from the average total Hg.

Table 5. Average values of mercury shallow sediment pore water parameters at various river miles for 2016-2017.

Average	RM 248	RM 286	RM 300	RM 310	RM 318	Total Avg
Total Hg (ng/l)	5.59	8.35	9.13	16.22	17.59	11.11
MeHg (ng/l)	1.62	2.77	3.38	1.81	1.45	2.34
HgII (ng/l) - Estimated	3.97	5.58	5.75	14.41	16.15	8.77

## **Atmospheric Deposition**

The atmospheric deposition rates for a variable with a unit of g/m³ (mg/l) are given in kg/km²/year. For Hg, since the state variable is in units of  $\mu$ g/m³ (ng/l), the atmospheric deposition rates are in units of mg/km²/year. No direct measurements were made during this study, but a study by Buetel, et al. (2021) estimated for Total Hg dry deposition:  $2.4 \pm 1.4$  ng/m² ·h ( $21 \mu$ g/m²/yr) and wet deposition of  $7.0 \pm 4.8$  ng/m² ·h ( $61 \mu$ g/m²/yr) for Pullman, WA, USA. These seem to be high values considering other studies such as Zhang et al. (2019) who showed that annual averages in the North America were  $9.1 \mu$ g/m²/yr for wet deposition and  $6.4 \mu$ g/m²/yr for dry deposition. Knightes et al. (2014) used a value of annual deposition of  $10 \mu$ g Hg/m²/yr with 98.5% HgII and 1.5% MeHg in a watershed Hg model.

## **Constituent Inputs**

Constituent concentrations for the Snake River inflow to Brownlee Reservoir were developed using Idaho Power Company (IPC) and USGS (USGS, 2021) data. Battelle data (included in the USGS data set) was used for the input files until August 2014. Data were collected from sampling stations located at RM 345.6. Data was not available for Powder River, Eagle Creek, or Burnt River during the simulation period, so input concentrations for these rivers were either set equal to Snake River inflow concentrations or regressions were developed to estimate certain parameters obtained by USGS and IPC. Regressions were created using either Snake River inflow concentrations of the same parameter or using tributary flows. The regressions that resulted in the best r-squared value were used for each site and for each parameter. Powder River input concentrations were calculated using a flow weighted average of Eagle Creek and Powder River concentrations near Richland, Oregon. Wildhorse River, Pine Creek, Daly Creek, and the distributed tributary concentrations were all set equal to flow weighted Powder River concentrations. Daily average flows for Snake River, Powder River, Burnt River, and Eagle Creek were calculated from the 15-minute input flows to use in the regressions and flow weighting. Table 6 lists all the tributaries in each model and segment location. Table 7 lists each of Hg constituents and methods to create the constituent inflow timeseries for the Snake River. Table 8 lists each of each of Hg constituents and the methods used to create the Hg constituent inflow timeseries for the Burnt River and Powder River. The regressions in Table 7 and Table 8 were originally determined from Harris (2022) but were later computed by PSU with updated USGS field data.

The following approach was used for processing data values for the input concentrations:

- USGS values with a "<" flag next to the reported value were halved when included in the inputs.
- IPC values with a "<" flag next to the reported value were halved when included in the inputs.
- Negative values and duplicates were removed.
- Any values of zero or "trace" were input as the minimum of (1) the lowest halved no detect ("<") value or (2) half of the lowest value observed (greater than zero).
- All other values were included as the value listed, including values flagged as suspect
  or estimates or were filtered in the laboratory prior to analysis. USGS values that were
  flagged with "< RL, estimate based on lowest standard" were also left at the value
  listed</li>
- If multiple values were recorded on the same day, the average value was used for the input.
- Gaps in data measurements were linearly interpolated except for when regressions were used as described in the tables below.

Interpolation was used to fill gaps in the data values for creating the model input timeseries.

Table 6. Modeled HCC inflows for the 3 models: Brownlee, Oxbow, and Hells Canyon.

Tributary	Model	Model Inflow Type, Number and Inflow Location
Snake River	Brownlee	Branch 1 Inflow, Segment 2
Powder River	Brownlee	Branch 6 Inflow, Segment 205
Burnt River	Brownlee	Tributary #1, Segment 62
Daly Creek	Brownlee	Tributary #2, Segment 207
Brownlee Water Balance Inflow	Brownlee	Branch 5 Distributed Tributary
Brownlee Dam Spill	Oxbow	Branch 1 Inflow, Segment 2
Wildhorse River	Oxbow	Tributary #1, Segment 6
Brownlee Turbines	Oxbow	Tributary #2, Segment 2

Tributary	Model	Model Inflow Type, Number and Inflow Location						
Oxbow Dam Spill and Bypass	Hells Canyon	Branch 1 Inflow, Segment 2						
Oxbow Turbines	Hells Canyon	Tributary #1, Segment 13						
Pine Creek	Hells Canyon	Tributary #2, Segment 15						

Table 7. Development of modeled constituent concentrations in Snake River inflows to Brownlee Reservoir. The constituent number is the number used in the CE-QUAL-W2 model.

#	Constituent	Comments
42	Hg0, ng/L	Set to constant 0.05
43	Hg(II), ng/L	Hg(II) was estimated from the sum of filtered and particulate HgII from USGS data: $ \Phi HgII_{model\ input} = \Phi HgII_{filt.data} + \Phi HgII_{part.data} $
44	MeHg, ng/L	MeHg was estimated from the sum of filtered and particulate MeHg from USGS data: $\Phi MeHg_{model\ input} = \Phi MeHg_{filt.data} + \Phi MeHg_{part.data}$

Table 8. Development of modeled constituent concentrations in the Burnt River and Powder River. Wildhorse River, Pine Creek, Daly Creek, and the distributed tributary concentrations were all set equal to flow weighted Powder River concentrations. The constituent number is the number used in the CE-QUAL-W2 model.

#	Constituent	Comments
42	Hg0, ng/L	Set to constant 0.05
43	Hg(II), ng/L	Burnt R., Powder R., and Eagle Cr. Hg(II) concentrations during the simulation period were estimated using a regression with Snake inflow filtered and particulate HgII concentrations from USGS data. Regressions were created using USGS HgII data available after the simulation period. Burnt River Regressions: $ \Phi HgII_{filt} = \exp\left(1.001 + 1.126\left(ln(\Phi HgII_{Snake\ filt})\right)\right) * 1.045 $ $ \Phi HgII_{part} = \exp\left(0.914 + 0.742\left(ln(\Phi HgII_{Snake\ part})\right)\right) * 1.171 $
		Powder River Regressions:
		$\Phi HgII_{filt} = \exp\left(0.542 + 0.969\left(ln(\Phi HgII_{Snake\ filt})\right)\right) * 1.045$

#	Constituent	Comments
		$\Phi HgII_{part} = \exp\left(-1.918 + 0.225\left(ln(\Phi HgII_{Snake\ part})\right)\right) * 1.588$
		Eagle Creek Regressions:
		HgII model inputs used the sum of filtered and particulate HgII as estimated from the regressions with Snake River data:
		$\Phi HgII_{model\;input} = \Phi HgII_{filt} + \Phi HgII_{part}$
44	MeHg, ng/L	Burnt R., Powder R., and Eagle Cr. MeHg concentrations during the simulation period were estimated using a regression with Snake inflow filtered and particulate MeHg concentrations from USGS data. Regressions were created using USGS MeHg data available after the simulation period.  Burnt River Regressions:
		$\Phi MeHg_{filt} = \exp\left(2.247 + 1.266\left(\ln(\Phi MeHg_{Snake\ filt})\right)\right) * 1.077$
		$\Phi MeHg_{part} = \exp\left(-0.415 + 0.606\left(ln(\Phi MeHg_{Snake\ part})\right)\right) * 1.349$
		Powder River Regressions:
		$ \Phi MeHg_{filt} = \exp\left(0.981 + 1.000\left(ln\left(\Phi MeHg_{Snake\ filt}\right)\right)\right) * 1.048 $
		$\Phi MeHg_{part} = \exp\left(-2.421 + 0.508\left(ln(\Phi MeHg_{Snake\ part})\right)\right) * 1.235$
		Eagle Creek Regressions:
		$\Phi MeHg_{filt} = \exp\left(-1.132 + 1.093\left(ln(\Phi MeHg_{Snake\ filt})\right)\right) * 1.200$
		$\Phi MeHg_{part} = \exp\left(-3.446 + 0.361\left(ln(\Phi MeHg_{Snake\ part})\right)\right) * 1.069$
		HgII model inputs used the sum of filtered and particulate HgII as estimated from the regressions with Snake River data:
		$\Phi MeHg_{model\;input} = \Phi MeHg_{filt} + \Phi MeHg_{part}$

Constituent input concentrations for the Snake River inflow and tributaries are shown in Figure 11.

Figure 11. Constituent concentrations for HgO, HgII, MeHg. Daly Creek, Brownlee Reservoir distributed tributary, Pine Creek, and Wildhorse River were set equal to Powder River concentrations.

## Model-Data Comparisons in Hells Canyon Complex

The water quality and hydrodynamic CE-QUAL-W2 model for the Hells Canyon Complex was compared to field data and results were summarized in Garstecki et al., 2023. Model results were compared to vertical profile data, outflow data, and sediment porewater data from IPC and USGS for the three reservoirs. Model-data comparisons were made for temperature, dissolved oxygen, pH, dissolved organic carbon, particulate organic carbon, chlorophyll a, zooplankton, nitrate, ammonia, TKN, TN, TP, dissolved ortho-phosphorus, chloride, oxidized and reduced Fe and Mn, CH<sub>4</sub>, H<sub>2</sub>S, sulfate, and suspended solids. Table 9 lists the locations with data used for outflow and profile model comparisons, and Table 10 lists the locations with USGS data used for sediment and porewater model comparisons. Brownlee Reservoir profile data were collected between (and including) river miles 327.8 to 286, Oxbow Reservoir profile data were collected at river mile 273, and Hells Canyon Reservoir profile data were collected between (and including) river miles 263.3 to 247.9. The following approach was used for processing data values for water quality comparisons:

- USGS values with a "<" flag next to the reported value were shown in figures as "no detects" at half the value listed and were omitted from statistics calculations.
- IPC values with a "<" flag next to the reported value were shown in figures as "no detects" at half the value listed in figures and omitted from statistics calculations.
- Negative values and duplicates were removed.
- Any values of zero or "trace" were shown on figures as the minimum of (1) the lowest halved no detect ("<") value or (2) half of the lowest value observed (greater than zero) and omitted from the statistics calculations.
- Negative depths were converted to positive and USGS depths of "SW" were converted to 0.3m. However, these only applied to inflow/outflow locations where flow was well-mixed and depth was not used for generating comparisons.
- All other values were included as the value listed, including values flagged as suspect
  or estimates or were filtered in the laboratory prior to analysis. USGS values that were
  flagged with "< RL, estimate based on lowest standard" were also left at the value
  listed.</li>

Table 9 and Table 10 also include Hg data that will be used for model-data comparisons.

# **Typical Hg Parameters Values**

Table 11 shows typical water column parameter values used in the Hg module in CE-QUAL-W2 many of which were suggested by Harris (2021). Table 12 shows typical Hg parameter values for the sediment model also many of which were suggested by Harris (2021). These values were used as starting points for the Hg model calibration.

#### [Add more literature values]

TABLE 11. HG PARAMETERS FOR THE WATER COLUMN.

Symbol	Description	Typical values	Units
ANOX	Fraction of anoxic to oxic decay rate used in computing JPOC	0.01-0.1. Lee (1992) suggests though that the rates of oxic and anoxic decomposition could be of a similar order of magnitude. Lee (1992) showed that this ratio varies from 0.04 to 1 depending on the location and organic compound. In most cases though the oxic decay rate was much larger than the anoxic one.	[-]
		Hg0

<b>K</b> pn-MeHg	MeHg equilibrium partition coefficients for inorganic solid group (silt, clay)	1e6	L kg <sup>-1</sup>

Symbol	Description	Typical values	Units
K <sub>demeth</sub> -sed	MeHg biological demethylation rate constant	Helmich et al. (2022) report a value of 0.5 d <sup>-1</sup> to 1.8 d <sup>-1</sup> for the overall decay rate for aquatic sediments which would be comparable to K <sub>demeth-sed</sub> JPOC2. EPA (2001) in a WASP application to Savannah River, Georgia used 2E-5 day <sup>-1</sup> which is an overall rate. Knightes et al. (2014) used overall maximum rates at 20°C of between 0.003-0.03 day <sup>-1</sup>	m³/g C decomposed

# Effect of Temperature on Methylation and Demethylation

Most researchers have used the Arrhenius method of adjusting methylation and demethylations rates by temperature. A summary of some of these studies are shown in Table 13 for methylation and demethylation.

Most studies report values in terms of  $Q_{10}$ , which is defined as

$$Q_{10} = \left(\frac{k_2}{k_1}\right)^{\frac{10}{T_2 - T_1}}$$

TABLE 13. METHYLATION AND DEMETHYLATION RATES AFFECTED BY TEMPERATURE.

Description	Q10	Base temperature, oC	Reference	Comments
Methylation	1.14	15	Knightes et al. (2014)	
	1.17 to 1.4	20	Harris and Beals (2012)	Used for temperatures between 20 and 30°C. Microbial activity was much higher with Q10 values between 2.1-3.63

Demethylation	1.04	20	Knightes et al. (2014)	
			Harris and Beals (2012)	

# **Summary**

This report summarizes the development of the Mercury model in CE-QUAL-W2 for the Hells Canyon complex (Brownlee Reservoir, Oxbow Reservoir, and Hells Canyon Reservoir) on the Snake River. The CE-QUAL-W2 model framework provides for horizontal and vertical advection and dispersion. The report describes the following:

- Hg module in CE-QUAL-W2 including state variables: Hg0 (elemental mercury), HgII (inorganic mercury), and MeHg (methylmercury). The model uses equilibrium partitioning of HgII and MeHg on solids. These solids include inorganic suspended solids, organic solids (refractory organic matter, RPOM, and labile particulate organic matter, LPOM), algae, and zooplankton. The Hg model was divided into a water column model and a bed sediment model and included these processes:
  - Water Column processes: photoreduction, photo-oxidation,
     photodegradation, volatilization, methylation, demethylation, diffusion to
     and from the sediment layer, and settling
  - Sediment processes: diffusion to and from the sediment bed, burial, methylation, demethylation
- Hg Bed Sediment Dynamics including its connection to the CE-QUAL-W2 sediment diagenesis model. The Hg sediment model uses temperature, organic solids concentrations, diffusion rates between the water and bed, and C turnover rates.

The report also describes the location of field data used for boundary conditions and for internal model-data comparisons. The process for computing time series of Hg0, HgII, and MeHg was described.

Also, a table was presented with model coefficient suggestions for calibration.

Appendix A presents a detailed overall of how to use the CE-QUAL-W2 Hg model and what input files and output files are required. Appendix B presents a section on non-equilibrium sorption if that is to be used in the future.

A companion report describing the Hg model calibration is currently under development.

# Appendix A: Implementation of Hg Model in CE-QUAL-W2

This Appendix describes how to turn use the Hg module in CE-QUAL-W2. The required input files described below are in the Excel macro-enabled worksheet as separate tabs that can be written out as input files to the CE-QUAL-W2 model. This section assumes familiarity with the CE-QUAL-W2 model and its User manual (Wells, 2023).

Input File: w2\_con.csv

The Hg module in CE-QUAL-W2 can be turned ON/OFF by following these steps:

1. In the w2\_con.csv tab, turn ON HG

w2_con.csv file format			CE-QUAL-W2 Ver	sion	4.5						
			Control File version	on	4.5	w2_con45	.csv				İ

4. If atmospheric deposition is used, make sure this is turned ON in the control file w2\_con.csv.

	AtmDep				
ATMOSPHERIC DEPOSITION	WB1	WB2	WB3	WB4	WB5
Atm_DepositionC - turn ON/OFF mass loading (kg/km2/year) for each water body	ON	ON	ON	ON	ON
Atm_Deposition_Interpolation - Interpolate between values ON/OFF	ON	ON	ON	ON	ON

5. KDO (half-saturation concentration of DO required for oxic decomposition ) is now a function of waterbody and new variable AANOX (fraction of aerobic decay rate). These are variables that affect methylation and demethylation.

SED CO2	WB1	WB2	WB3	WB4	WB5
CO2R Sediment carbon dioxide release rate, fraction of sediment oxygen demand	0.5	0.5	0.5	0.5	0.5
	O2LIMIT				
OXYGEN Limit	WB1	WB2	WB3	WB4	WB5
O2 LIMIT KDO, Dissolved oxygen half-saturation constant or concentration at which	0.2	0.2	0.2	0.2	0.2
AANOX, ratio of anoxic to oxic carbon decomposition rate (0 - 1)	0.1	0.1	0.1	0.1	0.1
	SODRATES				

6. In the tab w2\_Hg.csv, adjust model coefficients for Hg. Make sure you select the output file and click the button for exporting this file. This file is described in the next section.

Input file: w2\_Hg.csv

This is located in the Excel spreadsheet under the tab by that name as shown below:

... w2\_con.csv Required Constituent Order w2\_habitat.npt w2\_Hg.csv w2\_diagenesis.npt

This file contains the following input variables which are described in this report.

## Output Files Produced by the Hg Model

Flux output files for Hg processes include the time series files, flux output files, and spreadsheet profile files. In addition, the Hg variables are part of the W2\_Post post-processor for visualizing contours, animations, profiles, and time series.

#### Time series files for water column and Hg sediment bed

These files are turned ON when a tsr file is defined in the main control file w2\_con.csv. Hence, if the tsr file for the water column was <code>tsr\_37\_seg154.csv</code>, then there would be 2 additional files produced: <code>tsr\_37\_seg154\_BedHg.csv</code> (for the sediment bed) and <code>tsr\_37\_seg154\_Hg.csv</code> (for the water column). See the CE-QUAL-W2 User Manual (Wells, 2023) on how to turn ON the tsr file output.

Output for the water column includes the following (instantaneous values):

**JDAY** 

HgIId(ng/L)

HgIIdoc(ng/L)

HgIIpom(ng/L)

HgIIp1(ng/L)

HgIIp2(ng/L)

Hgllap1(ng/L)

HgIIap2(ng/L)

HgIIap3(ng/L)

Hgllzp1(ng/L)

HgIIpt(ng/L)

```

```
HgIIISSTot "HgII on all inorganic SS, ng/L"
```

HgIIPOMTot "HgII on all POM, ng/L"

Methylation "Methylation rate, ng/L/d"

Demethylation "Demethylation rate, ng/L/d"

MeHgAlgTot "MeHg on all algae, ng/L"

MeHgZooTot "MeHg on all zooplankton, ng/L"

MeHgISSTot "MeHg on all inorganic SS, ng/L"

MeHgPOMTot "MeHg on all POM, ng/L"

JOC "C turnover rate, gC/m3/d'

#### Spreadsheet output file

The spreadsheet output file is described in the CE-QUAL-W2 User Manual (Wells, 2023). This file includes profiles of all model state variables including Hg0, HgII, and MeHg as well as profiles of the Hg fluxes and JOC (the C turnover used in the methylation rate equation) for the water column and sediment bed.

For the water column, besides Hg0, HgII, and MeHg, the fluxes include:

Hg0 volatilization(ng/L/d)

Hg0 oxidation(ng/L/d)

HgII reduction(ng/L/d)

HgII methylation(ng/L/d)

HgII settling(ng/L/d)

HgII sediment transfer(ng/L/d)

MeHg degradation(ng/L/d)

MeHg demethylation(ng/L/d)

MeHg settling(ng/L/d)

MeHg sediment transfer(ng/L/d)

MeHg sediment transfer(ng/L/d)

JOC(gC/m3/d)

For the sediment bed, besides HgII, and MeHg, the fluxes include:

BedHgII methylation(ng/L/d)

BedHgII burial(ng/L/d)

BedHgII settling accumulation(

BedMeHg demethylation(ng/L/d)

BedMeHg burial(ng/L/d)

BedMeHg settling accumulation(ng/L/d)

JOC2(gC/m3/d)

#### Flux File Output

If Flux Output is On in the main control file, w2\_con.csv, then Hg flux rates are output in a file that includes average flux rates over time period defined in the input file. Specification of these fluxes is made in the W2\_Hg.csv file under sediment fluxes.

#### Withdrawal Output Files

If the withdrawal output (WDO) file is specified in the main control file, all Hg state variables (HgO, HgII, and MeHg) are written out for any withdrawal as well as all derived variables that are ON. These currently include:

PHgIIw "Particulate HgII-w, ng/L" "Particulate HgII-s, ng/g" PHglls PMeHgw "Particulate MeHg-w, ng/L" PMeHgs "Particulate MeHg-s, ng/g" DissHgII "Dissolved HgII + HgIIDOC, ng/L" "Dissolved MeHg + MeHgDOC, ng/L" DissMeHg HgIIAlgTot "HgII on all algae, ng/L" "HgII on all zooplankton, ng/L" HgIIZooTot "HgII on all inorganic SS, ng/L" HgIIISSTot HgIIPOMTot "HgII on all POM, ng/L" Methylation "Methylation rate, ng/L/d" Demethylation "Demethylation rate, ng/L/d" MeHgAlgTot "MeHg on all algae, ng/L" MeHgZooTot "MeHg on all zooplankton, ng/L" MeHgISSTot "MeHg on all inorganic SS, ng/L" "MeHg on all POM, ng/L" MeHgPOMTot JOC "C turnover rate, gC/m3/d'

# Appendix B: Non-equilibrium Partitioning

A future addition to this model may include non-equilibrium sorption of *HgII* onto organic and inorganic solids in the water column and active sediment layer is included in the Hg module. Under non-equilibrium partitioning, the concentrations of dissolved and adsorbed phases of *HgII* are simulated separately.

#### Water Column:

Three state variables are simulated for *HgII* species in the water column:

- Hgll<sub>d</sub>, concentration of dissolved Hgll in water (ng L<sup>-1</sup>)
- HgII<sub>pom2</sub>, kinetic (strongly bound) concentration of organic solid adsorbed HgII in water (ng L<sup>-1</sup>)
- $HgII_{pn2}$ , kinetic (strongly bound) concentration of inorganic solid "n" adsorbed HgII in water (ng L<sup>-1</sup>) (n = 1 to NSS)

Note: Both boundary and initial conditions of concentrations of above state variables (HgII<sub>d</sub>, HgII<sub>pom2</sub> and HgII<sub>pn2</sub>) are required.

Organic and inorganic solids attached *HgII* are simulated with two sites: exchangeable (fast) and kinetic (rate-limited) kinetics. The concentration of attached *HgII* consists of an exchangeable (fast) sorption and the other associated with kinetic (rate-limited) sorption rate constraint parts.

$$[HgII_{pom}] = [HgII_{pom1}] + [HgII_{pom2}]$$
(2.1a)

$$[HgII_p] = \sum_{1}^{NSS} \{ [HgII_{pn1}] + [HgII_{pn2}] \}$$
 (2.1b)

### 1) POM attached component of HgII:

Using the linear isotherm previously described, exchangeable concentration of organic solid adsorbed HgII in water is determined by:

$$[HgII_{pom1}] = 10^{-6} f_{pom} K_{pom-HgII}[POM][HgII_d]$$
 (2.2)

Where

 $f_{nom}$  is the fraction of exchange sites on organic solids assumed to be at equilibrium.

The source and sink rate equation for the POM attached kinetic component is stated as:

$$\frac{d[HgII_{pom2}]}{dt} = -\underbrace{\frac{dHgII_{pom2}}{dz}}_{settling} + \underbrace{\frac{dHgII_{pom2}}{dt}}_{sorption}$$
(2.3)

Where

$$\frac{dHgII_{pom2}}{dt} = k_{ads} \left( \frac{HgII_{pom1}}{f_{pom}} - \frac{HgII_{pom2}}{(1 - f_{pom})} \right) \quad for \quad \frac{HgII_{pom1}}{f_{pom}} > \frac{HgII_{pom2}}{(1 - f_{pom})}$$
 (2.4a)

$$\frac{\frac{dHgII_{pom2}}{dt}}{\underbrace{\frac{dt}{sorntion}}} = k_{des} \left( \frac{HgII_{pom1}}{f_{pom}} - \frac{HgII_{pom2}}{(1 - f_{pom})} \right) \quad for \quad \frac{HgII_{pom1}}{f_{pom}} < \frac{HgII_{pom2}}{(1 - f_{pom})}$$
(2.4b)

#### 2) Inorganic solids attached component of Hall:

Exchangeable concentration of inorganic solid group n adsorbed HgII in water

$$[HgII_{pn1}] = 10^{-6} f_{pn} K_{pn-HgII} [ISS_n]$$
 (2.5)

Where  $f_{pn}$  is the fraction of exchange sites on inorganic solid group n assumed to be at equilibrium.

The source and sink rate equation for the inorganic solid group n attached kinetic component:

$$\frac{d[HgII_{pn2}]}{dt} = -\frac{dHgII_{pn2}}{\underbrace{dz}} + \underbrace{\frac{dHgII_{pn2}}{dt}}_{sorption}$$
 (2.6)

where

$$\frac{dHgII_{pn2}}{dt} = k_{ads} \left( \frac{HgII_{pn1}}{f_{pn}} - \frac{HgII_{pn2}}{(1-f_{pn})} \right) \quad for \quad \frac{HgII_{pn1}}{f_{pn}} > \frac{HgII_{pn2}}{(1-f_{pn})}$$
 (2.7a)

$$\frac{dHgII_{pn2}}{dt} = k_{des} \left( \frac{HgII_{pn1}}{f_{pn}} - \frac{HgII_{pn2}}{(1-f_{pn})} \right) \quad for \quad \frac{HgII_{pom1}}{f_{pn}} < \frac{HgII_{pn2}}{(1-f_{pn})}$$
 (2.7b)

3) Dissolved phase, DOC complexed and algae attached phase of HgII:

$$R \frac{d[HgII_d]}{dt} = -\underbrace{HgII \rightarrow Hg0}_{\text{photoreduction}} + \underbrace{Hg0 \rightarrow HgII}_{\text{photo-oxidation}} - \underbrace{HgII \rightarrow MeHg}_{\text{methylation}} + \underbrace{MeHg \rightarrow HgII}_{\text{demethyation}} + \underbrace{HgII \rightarrow Bed}_{\text{diffusion}} - \underbrace{\frac{dHgII_{pom1}}{dz}}_{\text{settling}} - \underbrace{\sum_{1}^{N} \underbrace{\frac{dHgII_{pn1}}{dz}}_{\text{settling}} - \underbrace{\frac{dHgII_{pom2}}{dt}}_{\text{sorption}} - \underbrace{\sum_{1}^{N} \underbrace{\frac{dHgII_{pnn2}}{dt}}_{\text{sorption}}}_{\text{sorption}} + \underbrace{\underbrace{\frac{dHgII_{pom2}}{dt}}_{\text{sorption}} - \underbrace{\frac{dHgII_{pnn2}}{dt}}_{\text{sorption}} + \underbrace{\underbrace{\frac{dHgII_{pnn2}}{dt}}_{\text{sorption}}}_{\text{sorption}} + \underbrace{\underbrace{\frac{d$$

$$R = 1 + 10^{-6} \sum_{n=1}^{NAL} K_{apn-HgII}[A_{pn}] + 10^{-6} K_{doc-HgII}[DOC] + 10^{-6} f_{pom} K_{pom-HgII}[POM] + \sum_{n=1}^{NSS} 10^{-6} f_{pn} K_{pn-HgII}[ISS_n]$$
 (2.9)

Eq. 2.3, 2.6, and 2.8 will be solved to get  $HgII_d$ ,  $HgII_{pom2}$ ,  $HgII_{pn2}$ .

The concentration of the total (unfiltered) HgII in the water column is

$$[HgII] = R[HgII_d] + [HgII_{pom2}] + \sum_{1}^{NSS} [HgII_{pn2}]$$
 (2.10)

### **Active Sediment Layer**

Three state variables are simulated for *HgII* species in the active sediment layer:

- HqII2<sub>d</sub>, concentration of dissolved HgII in porewater (ng L<sup>-1</sup>)
- HgII2<sub>pom2</sub>, kinetic (slow) concentration of organic solid adsorbed HgII in sediment (ng L<sup>-1</sup>)
- $HgII2_{pn2}$ , kinetic (slow) concentration of inorganic solid "n" adsorbed HgII in water (ng L<sup>-1</sup>) (n = 1 to N)

Note: Only initial conditions of concentrations of above state variables (HgII2<sub>d</sub>, HgII2<sub>pom2</sub> and HgII2<sub>pn2</sub>) are required for the active sediment layer.

1) POM attached kinetic component of HgII:

$$\frac{d[HgII2_{pom2}]}{dt} = \underbrace{\frac{dHgII}{dz}}_{deposition} - \underbrace{\frac{dHgII2_{pom2}}{dz}}_{burial} + \underbrace{\frac{dHgII2_{pom2}}{dt}}_{sorption}$$
(2.11)

Where

$$\frac{dHgII2_{pom2}}{dt} = k_{ads} \left( \frac{HgII2_{pom1}}{f_{pom}} - \frac{HgII2_{pom2}}{(1-f_{pom})} \right) \quad for \quad \frac{HgII2_{pom1}}{f_{pom}} > \frac{HgII2_{pom2}}{(1-f_{pom})}$$

$$(2.12a)$$

$$\frac{dHgII2_{pom2}}{dt} = k_{des} \left( \frac{HgII2_{pom1}}{f_{pom}} - \frac{HgII2_{pom2}}{(1-f_{pom})} \right) \quad for \quad \frac{HgII2_{pom1}}{f_{pom}} < \frac{HgII2_{pom2}}{(1-f_{pom})}$$

$$(2.12b)$$

#### 2) inorganic solids attached HgII:

$$\frac{d[HgII2_{pn2}]}{dt} = \underbrace{\frac{dHgII}{dz}}_{deposition} - \underbrace{\frac{dHgII2_{pn2}}{dz}}_{burial} + \underbrace{\frac{dHgII2_{pn2}}{dt}}_{sorption}$$
(2.13)

where

$$\frac{\frac{dHgII2_{pn2}}{dt}}{\underbrace{\frac{dt}{sorntion}}} = k_{ads} \left( \frac{\frac{HgII2_{pn1}}{f_{pn}} - \frac{HgII2_{pn2}}{(1-f_{pn})}}{(1-f_{pn})} \right) \quad for \quad \frac{HgII2_{pn1}}{f_{pn}} > \frac{HgII2_{pn2}}{(1-f_{pn})}$$
(2.14a)

$$\underbrace{\frac{dHgII2_{pn2}}{dt}}_{sorption} = k_{des} \left( \frac{HgII2_{pn1}}{f_{pn}} - \frac{HgII2_{pn2}}{(1-f_{pn})} \right) \quad for \quad \frac{HgII2_{pn1}}{f_{pn}} < \frac{HgII2_{pn2}}{(1-f_{pn})} \tag{2.14b}$$

# 3) dissolved phase of HgII:

$$R2\frac{d [HgII2_d]}{dt} = \underbrace{MeHg2 \rightarrow HgII2}_{\text{demethyation}} - \underbrace{HgII2 \rightarrow MeHg2}_{\text{methylation}} - \underbrace{HgII \leftrightarrow HgII2}_{\text{diffusion}} + \underbrace{\frac{dHgII_{ap}}{dz}}_{\text{deposition}} + \underbrace{\frac{dHgII_{pom1}}{dz}}_{\text{deposition}} - \underbrace{\frac{dHgII_{pom2}}{dt}}_{\text{sorption}} - \underbrace{\sum_{1}^{N} \frac{dHgII_{2pom2}}{dt}}_{\text{sorption}} - \underbrace{\sum_{1}^{N} \frac{dHgII2_{pn2}}{dt}}_{\text{sorption}}$$

$$(2.15)$$

$$R2 = 1 + 10^{-6} K_{doc-Hgll}[DOC2] + 10^{-6} f_{pom} K_{pom-HgII}[POM2] + \sum_{n=1}^{NSS} 10^{-6} f_{pn} K_{pn-HgII}[ISS2_n]$$
 (2.16)

The concentration of the total (unfiltered) HgII in the active sediment layer is

$$[HgII2] = R2[HgII_{2d}] + + [HgII2_{pom2}] + \sum_{1}^{NSS} [HgII2_{pn2}]$$
 (2.17)
